Hilbert C^* -modules and the Multiplier Algebra

In this chapter we introduce some of the fundamental theory of Hilbert C^* -modules, which may be thought of as a generalization of Hilbert spaces. The primary source of inspiration and techniques are the excellent books on the subject: [RW98], [Lan95] and [Mur14]. After reviewing the basic definitions we will proceed to construct and prove theorems regarding the Multiplier Algebra, which plays a crucial part in the development of the theory of the general crossed product, one of the basic constructions of this thesis.

1.1 HILBERT C^* -MODULES

Given a non-unital C^* -algebra A , we can extend a lot of the theory of unital C^* -algebras to A by considering the unitalization $A^\dagger = A + 1\mathbb{C}$ with the canonical operations. This is the 'smallest' unitalization in the sense that A the inclusion map is non-degenerate and maps A to an ideal of A^\dagger such that $A^\dagger/A \cong \mathbb{C}$. We can also consider a maximal unitalization, called the *Multiplier Algebra* of A , denoted by $M(A)$. We will now construct it and some theory revolving it, in particular that of Hilbert-modules:

Definition 1.1. Let A be any C^* -algebra. An *inner-product A -module* is a complex vector space E which is also a right- A -module which is equipped with a map $\langle \cdot, \cdot \rangle_A: E \times A \rightarrow A$ such that for $x, y, z \in E$, $\alpha, \beta \in \mathbb{C}$ and $a \in A$ we have

$$\langle a, \alpha y + \beta z \rangle_A = \alpha \langle a, y \rangle_A + \beta \langle a, z \rangle_A \quad (1.1)$$

$$\langle x, y \cdot a \rangle_A = \langle x, y \rangle_A \cdot a \quad (1.2)$$

$$\langle y, x \rangle_A = \langle x, y \rangle_A^* \quad (1.3)$$

$$\langle x, x \rangle_A \geq 0 \quad (1.4)$$

$$\langle x, x \rangle_A = 0 \implies x = 0. \quad (1.5)$$

If $\langle \cdot, \cdot \rangle$ satisfy (1.1)-(1.4) but not (1.5) above, we say that E is a *semi-inner-product A -module*. If there is no confusion, we simply write $\langle \cdot, \cdot \rangle$ to mean the A -valued inner-product on E . Similarly, we will often denote $x \cdot a$ by xa .

There is of course a corresponding version of left inner-product A -modules, with the above conditions adjusted suitably. However, we will unless otherwise specified always mean a right A -module in the following.

It is easy to see that this generalizes the notion of Hilbert spaces, for if $A = \mathbb{C}$, then any Hilbert space (over \mathbb{C}) is a inner-product \mathbb{C} -module. Even when E is only a semi-inner-product A -module, we still have a lot of the nice properties of regular inner-producte, e.g.:

Proposition 1.2 (Cauchy-Schwarz Inequality). Let E be a semi-inner-product A -module. For $x, y \in E$, it holds that

$$\langle x, y \rangle^* \langle x, y \rangle \leq \|\langle x, x \rangle\|_A \langle y, y \rangle.$$

Proof.

Let $x, y \in E$ and let $a = \langle x, y \rangle \in A$ and $t > 0$. Then, since $(\langle x, y \rangle a)^* = a^* \langle y, x \rangle$, we have

$$0 \leq \langle xa - ty, xa - ty \rangle = t^2 \langle y, y \rangle + a^* \langle x, x \rangle a - 2ta^* a.$$

For $c \geq 0$ in A , it holds that $a^* c a \leq \|c\|_A a^* a$: Let $A \subseteq \mathbb{B}(\mathcal{H})$ faithfully. The regular Cauchy-Schwarz implies that $\langle a^* c a \xi, \xi \rangle_{\mathcal{H}} \leq \|c\| \langle a^* a \xi, \xi \rangle_{\mathcal{H}}$ for all $\xi \in \mathcal{H}$. With this in mind, we then have

$$0 \leq a^* a \|\langle x, x \rangle\|_A - 2ta^* a + t^2 \langle y, y \rangle.$$

If $\langle x, x \rangle = 0$, then $0 \leq 2a^* a \leq t \langle y, y \rangle \rightarrow 0$, as $t \rightarrow 0$ so that $a^* a = 0$ as wanted. If $\langle x, x \rangle \neq 0$, then $t = \|\langle x, x \rangle\|_A$ gives the wanted inequality. \square

Recall that for $0 \leq a \leq b \in A$, it holds that $\|a\|_A \leq \|b\|_A$. This and the above implies that $\|\langle x, y \rangle\|_A^2 \leq \|\langle x, x \rangle\|_A \|\langle y, y \rangle\|_A$.

Definition 1.3. If E is an (semi-)inner-product A -module, we define a (semi-)norm on E by

$$\|x\| := \|\langle x, x \rangle\|_A^{\frac{1}{2}}, \text{ for } x \in E.$$

If E is an inner-product A -module such that this norm is complete, we say that E is a *Hilbert C^* -module over A* or just a *Hilbert A -module*.

If the above defined norm is but a semi-norm, then we may form the quotient space of E with respect to $N = \{x \in E \mid \langle x, x \rangle = 0\}$ to obtain an inner-product A -module with the obvious operations. Moreover, the usual ways of passing from pre-Hilbert spaces extend naturally to pre-Hilbert A -modules. For $x \in E$ and $a \in A$, we see that

$$\|xa\|^2 = \left\| a^* \underbrace{\langle x, x \rangle}_{\geq 0} a \right\| \leq \|a\|^2 \|x\|^2,$$

so that $\|xa\| \leq \|x\| \|a\|$, which shows that E is a normed A -module. For $a \in A$, let $R_a: x \mapsto xa \in E$. Then R_a is a linear map on E satisfying $\|R_a\| = \sup_{\|x\|=1} \|xa\| \leq \|a\|$, and the map $R: a \mapsto R_a$ is a contractive anti-homomorphism of A into the space of bounded linear maps on E (anti in the sense that $R_{ab} = R_b R_a$ for $a, b \in A$).

Example 1.4

The classic example of a Hilbert A -module is A itself with $\langle a, b \rangle = a^*b$, for $a, b \in A$. We will write A_A to specify that we consider A as a Hilbert A -module.

For a Hilbert A -module E , we let $\langle E, E \rangle = \text{Span} \{ \langle x, y \rangle \mid x, y \in E \}$. It is not hard to see that $\langle E, E \rangle$ is a closed ideal in A , and moreover, we see that:

Lemma 1.5. The set $E\langle E, E \rangle$ is dense in E .

Proof.

Let (u_i) denote an approximate unit for $\langle E, E \rangle$. Then clearly $\langle x - xu_i, x - xu_i \rangle \rightarrow 0$ for $x \in E$ (seen by expanding the expression), which implies that $xu_i \rightarrow x$ in E \square

In fact, the above proof also shows that EA is dense in E and that $x1 = x$ when $1 \in A$.

Definition 1.6. If $\langle E, E \rangle$ is dense in A we say that the Hilbert A -module is *full*.

Note

There are similarities and differences between Hilbert A -modules and regular Hilbert spaces. One major difference is that for closed submodules $F \subseteq E$, it does not hold that $F \oplus F^\perp = E$, where $F^\perp = \{y \in E \mid \langle x, y \rangle = 0, x \in F\}$: Let $A = C([0, 1])$ and consider A_A . Let $F \subseteq A$ be the set $F = \{f \in A_A \mid f(0) = f(1) = 0\}$. Then F is clearly a closed sub A -module of A_A . Consider the element $f \in F$ given by

$$f(t) = \begin{cases} t & t \in [0, \frac{1}{2}] \\ 1 - t & t \in (\frac{1}{2}, 1] \end{cases}$$

For all $g \in F^\perp$ it holds that $\langle f, g \rangle = fg = 0$, so $g(t) = 0$ for $t \in (0, 1)$ and by uniform continuity on all of $[0, 1]$, from which we deduce that $F^\perp = \{0\}$ showing that $A \neq F \oplus F^\perp$. The number of important results in the theory of Hilbert spaces relying on the fact that $\mathcal{H} = F^\perp \oplus F$ for closed subspaces F of \mathcal{H} is enormous, and hence we do not have the entirety of our usual toolbox available.

However, returning to the general case, we are pleased to see that it does hold for Hilbert A -modules E that for $x \in E$ we have

$$\|x\| = \sup \{ \|\langle x, y \rangle\| \mid y \in E, \|y\| \leq 1 \}. \quad (\star)$$

This is an obvious consequence of the Cauchy-Schwarz theorem for Hilbert A -modules.

Another huge difference is that adjoints don't automatically exist: Let $A = C([0, 1])$ again and F as before. Let $\iota: F \rightarrow A$ be the inclusion map. Clearly ι is a linear map from F to A , however, if it had an adjoint $\iota^*: A \rightarrow F$, then for any self-adjoint $f \in F$, we have

$$f = \langle \iota(f), 1 \rangle_A = \langle f, \iota^*(1) \rangle = f\iota^*(1),$$

so $\iota^*(1) = 1$, but $1 \notin F$. Hence ι^* is not adjointable. We shall investigate properties of the adjointable operators in more detail further on.

closedness under
direct sum and
 $\mathcal{H}_A = \mathcal{H} \otimes A$

1.2 THE C^* -ALGEBRA OF ADJOINTABLE OPERATORS

The set of adjointable maps between Hilbert A -modules is of great importance and has many nice properties, and while not all results carry over from the theory of bounded operators on a Hilbert space, many do, as we shall see.

Definition 1.7. For Hilbert A -modules E_i with A -valued inner-products $\langle \cdot, \cdot \rangle_i$, $i = 1, 2$, we define $\mathcal{L}_A(E_1, E_2)$ to be the set of all maps $t: E_1 \rightarrow E_2$ for which there exists a map $t^*: E_2 \rightarrow E_1$ such that

$$\langle tx, y \rangle_2 = \langle x, t^*y \rangle_1,$$

for all $x \in E_1$ and $y \in E_2$, i.e., *adjointable maps*. When no confusion may occur, we will write $\mathcal{L}(E_1, E_2)$ and omit the subscript.

Proposition 1.8. if $t \in \mathcal{L}(E_1, E_2)$, then

1. t is A -linear and
2. t is a bounded map.

Proof.

Linearity is clear. To see A -linearity, note that for $x_1, x_2 \in E_i$ and $a \in A$ we have $a^* \langle x_1, x_2 \rangle_i = \langle x_1 a, x_2 \rangle_i$, and hence for $x \in E_1$, $y \in E_2$ and $a \in A$ we have $\langle t(xa), y \rangle_2 = a^* \langle x, t^*(y) \rangle_1 = \langle t(x)a, y \rangle_1$.

To see that t is bounded, we note that T has closed graph: Let $x_n \rightarrow x$ in E_1 and assume that $tx_n \rightarrow z \in E_2$. Then

$$\langle tx_n, y \rangle_2 = \langle x_n, t^*y \rangle_1 \rightarrow \langle x, t^*y \rangle_1 = \langle tx, y \rangle_2$$

so $tx = z$, and hence t is bounded, by the Closed Graph Theorem (CGT hereonforth). \square

In particular, similar to the way that the algebra $\mathbb{B}(\mathcal{H}) = \mathcal{L}_{\mathbb{C}}(\mathcal{H}_{\mathbb{C}}, \mathcal{H}_{\mathbb{C}})$ is of great importance, we examine the for a fixed Hilbert A -module E , the $*$ -subalgebra $\mathcal{L}(E) := \mathcal{L}(E, E)$ of bounded operators on E :

Proposition 1.9. The algebra $\mathcal{L}(E)$ is a closed $*$ -subalgebra of $\mathbb{B}(E)$ such that for $t \in \mathcal{L}(E)$ we have

$$\|t^*t\| = \|t\|^2,$$

hence is it a C^* -algebra.

Proof.

Since $\mathbb{B}(E)$ is a Banach algebra, we have $\|t^*t\| \leq \|t^*\| \|t\|$ for all $t \in \mathcal{L}(E)$. Moreover, by Cauchy-Schwarz, we have

$$\|t^*t\| = \sup_{\|x\| \leq 1} \{\|t^*tx\|\} = \sup_{\|x\|, \|y\| \leq 1} \{\langle tx, ty \rangle\} \geq \sup_{\|x\| \leq 1} \{\|\langle tx, tx \rangle\|\} = \|t\|^2,$$

so $\|t^*t\| = \|t\|^2$. Assume that $t \neq 0$, then we see that $\|t\| = \|t^*t\| \|t\|^{-1} \leq \|t^*\|$ and similarly $\|t^*\| \leq \|t^{**}\| = \|t\|$, so $\|t\| = \|t^*\|$, in particular $t \mapsto t^*$ is continuous. It is clear that $\mathcal{L}(E)$ is a $*$ -subalgebra. To see that it is closed, suppose that (t_α) is a Cauchy-net, and denote its limit by $t \in \mathbb{B}(E)$. By the above, we see that (t_α^*) is Cauchy with limit $f \in \mathbb{B}(E)$, since Then, we see that for all $x, y \in E$

$$\langle tx, y \rangle = \lim_\alpha \langle t_\alpha x, y \rangle = \lim_\alpha \langle x, t_\alpha^* y \rangle = \langle x, fy \rangle,$$

so t is adjointable, hence an element of $\mathcal{L}(E)$. \square

If we for $x \in E$ denote the element $\langle x, x \rangle^{\frac{1}{2}} \geq 0$ by $|x|_A$, then we obtain a variant of a classic and important inequality:

Lemma 1.10. Let $t \in \mathcal{L}(E)$, then $|tx|^2 \leq \|t\|^2 |x|^2$ for all $x \in E$.

Proof.

The operator $\|t\|^2 - t^*t \geq 0$, since $\mathcal{L}(E)$ is a C^* -algebra, and thus equal to s^*s for some $s \in \mathcal{L}(E)$. Hence

$$\|t\|^2 \langle x, x \rangle - \langle t^*tx, x \rangle = \langle (\|t\|^2 - t^*t)x, x \rangle = \langle sx, sx \rangle \geq 0,$$

for all $x \in E$, as wanted. \square

A quite useful result about positive operators on a Hilbert space carries over to the case of Hilbert C^* -modules, for we have:

Lemma 1.11. Let E be a Hilbert A -module and let T be a linear operator on E . Then T is a positive operator in $\mathcal{L}_A(E)$ if and only if for all $x \in E$ it holds that $\langle Tx, x \rangle \geq 0$ in A .

Proof.

If T is adjointable and positive, then $T = S^*S$ for some $S \in \mathcal{L}(E)$ and $\langle Tx, x \rangle = \langle Sx, Sx \rangle \geq 0$. For the converse, we note first that the usual polarization identity applies to Hilbert C^* -modules as well:

$$4\langle x, y \rangle = \sum_{k=0}^3 i^k \langle u + i^k v, u + i^k v \rangle,$$

for all $u, v \in E$, since $\langle u, v \rangle = \langle v, u \rangle^*$. Hence, if $\langle Tx, x \rangle \geq 0$ for all $x \in E$, we see that $\langle Tx, x \rangle = \langle x, Tx \rangle$, so

$$4\langle Tx, y \rangle = \sum_{k=0}^3 i^k \underbrace{\langle T(x + i^k y), x + i^k y \rangle}_{=\langle x + i^k y, T(x + i^k y) \rangle} = 4\langle x, Ty \rangle, \text{ for } x, y \in E.$$

Thus $T = T^*$ is an adjoint of T and $T \in \mathcal{L}_A(E)$. An application of the continuous functional calculus allows us to write $T = T^+ - T^-$ for positive operators $T^+, T^- \in \mathcal{L}_A(E)$ with $T^+T^- = T^-T^+ = 0$, see e.g., [Zhu93, Theorem 11.2]. Then, for all $x \in E$ we have

$$0 \leq \langle TT^-x, x \rangle = \langle -(T^-)^2x, T^-x \rangle = -\underbrace{\langle (T^-)^3x, x \rangle}_{\geq 0} \leq 0,$$

so $\langle (T^-)^3 x, x \rangle = 0$ for all x . The polarization identity shows that $(T^-)^3 = 0$ and hence $(T^-) = 0$, so $T = T^+ \geq 0$. \square

And, as in the Hilbert Space situation, we also have

Lemma 1.12. Let E be a Hilbert A -module and $T \geq 0$ in $\mathcal{L}_A(E)$. Then

$$\|T\| = \sup_{\|x\| \leq 1} \{\|\langle Tx, x \rangle\|\}$$

Proof.

Write $T = S^*S$ for $S \in \mathcal{L}_A(E)$ to obtain the identity. \square

It is well-known that the only ideal of $\mathbb{B}(\mathcal{H})$ is the set of compact operators, $\mathbb{K}(\mathcal{H})$, which is the norm closure of the finite-rank operators. We now examine the Hilbert C^* -module analogue of these two subsets:

Definition 1.13. Let E, F be Hilbert A -modules. Given $x \in E$ and $y \in F$, we let $\Theta_{x,y}: F \rightarrow E$ be the map

$$\Theta_{x,y}(z) := x\langle y, z \rangle,$$

for $z \in F$. It is easy to see that $\Theta_{x,y} \in \mathbb{B}(F, E)$.

Proposition 1.14. Let E, F be Hilbert A -modules. Then for every $x \in E$ and $y \in F$, it holds that $\Theta_{x,y} \in \mathcal{L}(F, E)$. Moreover, if H is another Hilbert A -module, then

1. $\Theta_{x,y}\Theta_{u,v} = \Theta_{x\langle y, u \rangle_F, v} = \Theta_{x, v\langle u, y \rangle_F}$, for $u \in F$ and $v \in G$,
2. $T\Theta_{x,y} = \Theta_{Tx, y}$, for $T \in \mathcal{L}(E, G)$,
3. $\Theta_{x,y}S = \Theta_{x, S^*y}$ for $S \in \mathcal{L}(G, F)$.

Proof.

Let $x, w \in E$ and $y, u \in F$ for Hilbert A -modules E, F as above. Then, we see that

$$\langle \Theta_{x,y}(u), w \rangle_E = \langle x\langle y, u \rangle_F, w \rangle_E = \langle u, y \rangle_F \langle x, w \rangle_E = \langle u, y\langle x, w \rangle_E \rangle_F,$$

so $\Theta_{x,y}^* = \Theta_{y,x} \in \mathcal{L}(E, F)$. Suppose that G is another Hilbert A -module and $v \in G$ is arbitrary, then

$$\Theta_{x,y}\Theta_{u,v}(g) = x\langle y, u\langle v, g \rangle_G \rangle_F = x\langle y, u \rangle_F \langle v, g \rangle = \Theta_{x\langle y, u \rangle_F, v}(g),$$

for $g \in G$. The other identity in (1) follows analogously. Let $T \in \mathcal{L}(E, G)$, then

$$T\Theta_{x,y}(u) = Tx\langle y, u \rangle_F = \Theta_{Tx, y}(u),$$

so (2) holds and (3) follows analogously. \square

Definition 1.15. Let E, F be Hilbert A -modules. We define the set of compact operators $F \rightarrow E$ to be the set

$$\mathbb{K}_A(F, E) := \overline{\text{Span}\{\Theta_{x,y} \mid x \in E, y \in F\}} \subseteq \mathcal{L}_A(F, E).$$

It follows that for $E = F$, the $*$ -subalgebra of $\mathcal{L}_A(E)$ obtained by taking the span of $\{\Theta_{x,y} \mid x, y \in E\}$ forms a two-sided algebraic ideal of $\mathcal{L}_A(E)$, and hence its closure is a C^* -algebra:

Definition 1.16. For a Hilbert A -module E , we define the compact operators on E to be the C^* -algebra

$$\mathbb{K}_A(E) := \overline{\text{Span}\{\Theta_{x,y} \mid x, y \in E\}} \subseteq \mathcal{L}_A(E).$$

Note

An operator $t \in \mathbb{K}_A(F, E)$ need not be a compact operator when E, F are considered as Banach spaces, i.e., a limit of finite-rank operators. This is easy to see by assuming that A is unital: The operator $\text{id}_A = \Theta_{1,1}$ is in $\mathbb{K}_A(A_A)$, but the identity operator is not a compact operator on an infinite-dimensional Banach space.

Lemma 1.17. There is an isomorphism $A \cong \mathbb{K}_A(A_A)$. If A is unital, then $\mathbb{K}_A(A_A) = \mathcal{L}_A(A_A)$.

Proof.

Fix $a \in A$ and define $L_a : A \rightarrow A$ by $L_a(b) = ab$. Then $\langle L_a x, y \rangle = x^* a^* y = \langle x, L_{a^*} y \rangle$ for all $x, y \in A$, hence L_a is adjointable with adjoint L_{a^*} . Note that $L_{ab^*}(x) = ab^* x = a \langle b, x \rangle = \Theta_{a,b}(x)$ for $a, b, x \in A$, hence if $L : a \mapsto L_a$, we have $\mathbb{K}_A(A_A) \subseteq \text{Im}(L)$. It is clear that L is a $*$ -homomorphism of norm one, i.e., an isometric homomorphism, so its image is a C^* -algebra. To see that it has image equal to $\mathbb{K}_A(A_A)$, let (u_i) be an approximate identity of A . Then for any $a \in A$ $L_{u_i a} \rightarrow L_a$, and since $L_{u_i a} \in \mathbb{K}_A(A_A)$ for all i , we see that $L_a \in \mathbb{K}_A(A_A)$. If $1 \in A$, then for $t \in \mathcal{L}_A(A_A)$ we see that $t(a) = t(1 \cdot a) = t(1) \cdot a = L_{t(1)} a$, so $t \in \mathbb{K}_A(A_A)$, and $\mathcal{L}_A(A_A) \cong A$. \square

Note

It does not hold in general that $A \cong \mathcal{L}_A(A_A)$.

In 1.5 we saw that for a Hilbert A -module E , the set $E\langle E, E \rangle$ was dense in E . We are going to improve this to say that every $x \in E$ is of the form $y\langle y, y \rangle$ for some unique $y \in E$. To do this, we need to examine the compact operators a bit more:

add source org [6]
morita

Proposition 1.18. Given a right Hilbert A -module E , then E is a full left Hilbert $\mathbb{K}_A(E)$ -module with respect to the action $T \cdot x = T(x)$ for $x \in E$ and $T \in \mathbb{K}_A(E)$ and $\mathbb{K}_A(E)$ -valued inner product $\langle x, y \rangle_{\mathbb{K}_A(E)} = \Theta_{x,y}$ for $x, y \in E$. Moreover, the corresponding norm $\|\cdot\|_{\mathbb{K}_A(E)} = \|\langle \cdot, \cdot \rangle_{\mathbb{K}_A(E)}\|^{\frac{1}{2}}$ coincides with the norm $\|\cdot\|_A$ on E .

Proof.

It is easy to see that the first, second and third condition of 1.1 are satisfied in light of 1.14. Note that

$$\langle \mathbb{K}_A(E) \langle x, x \rangle \cdot y, y \rangle_A = \langle x \langle x, y \rangle, y \rangle_A = \langle x, y \rangle_A^* \langle x, y \rangle_A \geq 0, \quad (1.6)$$

for all $x, y \in E$, which by 1.11 implies $\mathbb{K}_A(E) \langle x, x \rangle \geq 0$ for all $x \in E$. The above calculation also shows that if $\mathbb{K}_A(E) \langle x, x \rangle = 0$ then $\langle x, y \rangle_A = 0$ for all $y \in E$ so $x = 0$.

To see the last condition, note that

$$\| \langle \mathbb{K}_A(E) \langle x, x \rangle x, x \rangle_A \| = \| \langle x, x \rangle_A^* \langle x, x \rangle_A \| = \| x \|_A^2$$

so by 1.12, $\| x \|_{\mathbb{K}_A(E)} \geq \| x \|_A$ for all $x \in E$. For the other inequality, applying Cauchy-Schwarz to 1.6, we see that

$$\langle \mathbb{K}_A(E) \langle x, x \rangle y, y \rangle_A \leq \| \langle x, x \rangle_A \| \langle y, y \rangle_A$$

so again by 1.12 we see that $\| \mathbb{K}_A(E) \langle x, x \rangle \| \leq \| \langle x, x \rangle_A \|$ for all $x \in E$. \square

When we considered $E = A_A$, we defined for $a \in A$ the operator $L_a : b \mapsto ab$, $b \in A$. Similarly, we do this in the general case:

Definition 1.19. Let E be a Hilbert A -module. We define for $x \in E$ the operators $L_x : A \rightarrow E$, $a \mapsto x \cdot a$, and $D_x : E \rightarrow A$, $y \mapsto \langle x, y \rangle_A$.

Remark

The calculation

$$\langle D_x(y), a \rangle_{A_A} = \langle \langle x, y \rangle_A^* a, a \rangle_{A_A} = \langle y, x \rangle_A a = \langle y, xa \rangle_A = \langle y, L_x(a) \rangle_{A_A},$$

for $x, y \in E$ and $a \in A$ shows that L_x and D_x are mutual adjoints, so $L_x \in \mathcal{L}_A(A_A, E)$ and $D_x \in \mathcal{L}_A(E, A_A)$.

In fact, the maps $D : x \mapsto D_x$ and $L : x \mapsto L_x$ are interesting on their own, which extends the result from the case $E = A_A$ seen in 1.17:

Lemma 1.20. Let E be a Hilbert A -module. Then D is a conjugate linear isometric isomorphism of E and $\mathbb{K}_A(X, A_A)$ and L is a linear isometric isomorphism of E and $\mathbb{K}_A(A_A, E)$.

Proof.

By the conjugate linearity of $\langle \cdot, y \rangle_A$ for all $y \in E$, it is easy to see that D is conjugate linear. By (\star) , we see that $\| D_x \| = \| x \|$ for all $x \in E$, which implies that the image of D is closed. For $a \in A$ and $x \in E$, note that $\mathbb{K}_A(E, A_A) \ni \Theta_{a,x} = D_{x \cdot a}^*$, which implies that $\mathbb{K}_A(E, A_A) = D(E)$, by continuity of D and density of $E \langle E, E \rangle$ in E : Let $x \in E$ and (e_i) be an approximate unit of $\langle E, E \rangle$. Then $D_x = \lim D_{xe_i} = \lim \Theta_{x,e_i}$.

The second statement follows since clearly $L : x \mapsto D_x^*$ is then a linear isometry and we saw in 1.14 that $\Theta_{a,x}^* = \Theta_{x,a}$, so the argument above applies to L as well. \square

Abusing notation, we will in the following use L_x to denote both the operator on E and A_A depending on the location of x . We now show a generalization of a standard trick regarding operators on direct sums of Hilbert spaces: Recall that we may view $\mathbb{B}(\mathcal{H} \oplus \mathcal{K})$ as the set of matrices

$$\begin{pmatrix} \mathbb{B}(\mathcal{H}) & \mathbb{B}(\mathcal{K}, \mathcal{H}) \\ \mathbb{B}(\mathcal{H}, \mathcal{K}) & \mathbb{B}(\mathcal{K}) \end{pmatrix}$$

by compression with the orthogonal projection onto e.g. \mathcal{H} . This also holds for the compact operators on $\mathcal{H} \oplus \mathcal{K}$, and more generally:

Lemma 1.21. Let E be a Hilbert A -module. If $L_a \in \mathbb{K}_A(A_A)$, $S \in \mathbb{K}_A(A_A, E)$, $T \in \mathbb{K}_A(E, A_A)$ and $R \in \mathbb{K}_A(E)$, then

$$Q := \begin{pmatrix} L_a & T \\ S & R \end{pmatrix} \in \mathbb{K}_A(A_A \oplus E),$$

and its adjoint is

$$Q^* = \begin{pmatrix} L_a^* & S^* \\ T^* & R^* \end{pmatrix}$$

Moreover, every compact operator on $A_A \oplus E$ is of this form. If $Q \in \mathbb{K}_A(A_A \oplus E)$ is self-adjoint and anti-commutes with $1 \oplus -1$ then

$$Q = \begin{pmatrix} 0 & D_x \\ L_x & 0 \end{pmatrix},$$

for some $x \in E$ and L_x, D_x as in Lemma 1.20.

Proof.

It is clear that Q is adjointable with adjoint

$$Q^* = \begin{pmatrix} L_a^* & S^* \\ T^* & R^* \end{pmatrix}$$

To see that it is compact, note that each of the four corner embeddings

$$L_a \mapsto \begin{pmatrix} L_a & 0 \\ 0 & 0 \end{pmatrix}, \quad T \mapsto \begin{pmatrix} 0 & T \\ 0 & 0 \end{pmatrix}, \quad S \mapsto \begin{pmatrix} 0 & 0 \\ S & 0 \end{pmatrix}, \quad R \mapsto \begin{pmatrix} 0 & 0 \\ 0 & R \end{pmatrix}$$

are linear isometries and they map the module valued finite-rank maps to module valued finite-rank maps, e.g., we see that $\Theta_{a,x} \in \mathbb{K}_A(E, A)$ is mapped to $\Theta_{(a,0),(x,0)}$. By compressing with the orthogonal projection onto e.g., A_A , we see that we can decompose every finite rank operator in this way. Since compression by projections is continuous, this shows that every compact operator has this form.

The last statement follows readily from the isomorphism from Lemma 1.20, the anti-commutativity forces $L_a = 0$ and $R = 0$ and self-adjointness forces $D_x^* = L_x$. □

add as example
projection module

We may finally prove the statement which we set out to show:

Proposition 1.22. Let E be a Hilbert A -module. Then for every $x \in E$ there is a unique $y \in E$ such that $x = y\langle y, y \rangle$.

Proof.

Let $x \in E$, and consider the self-adjoint operator

$$t = \begin{pmatrix} 0 & D_x \\ L_x & 0 \end{pmatrix}$$

on $A_A \oplus E$, which by Lemma 1.21 is self-adjoint and anti-commutes with $1 \oplus -1$. With t being self-adjoint, the function $f(x) = x^{\frac{1}{3}}$ is continuous on the spectrum $\sigma(t)$, so it defines a compact operator $f(t)$ on $A_A \oplus E$. This operator anti-commutes with $1 \oplus -1$ by the functional calculus applied to the map $\psi: \mathbb{K}_A(A_A \oplus E) \rightarrow \mathbb{K}_A(A_A \oplus E)$, $s \mapsto (1 \oplus -1)s + s(1 \oplus -1)$, which is a $*$ -homomorphism, so there is $y \in E$ such that

$$f(t) = \begin{pmatrix} 0 & D_y \\ L_y & 0 \end{pmatrix}$$

And so $f(t)^3 = t$ implies that $L_x = L_y D_y L_y = L_{y\langle y, y \rangle}$, so $x = y\langle y, y \rangle$. \square

We impose quite an assortment of topologies on $\mathbb{B}(\mathcal{H}, \mathcal{H}')$ for Hilbert spaces \mathcal{H} and \mathcal{H}' – this is not the case when we study Hilbert C^* -modules: Given Hilbert A -module E and F , we only consider two topologies – the norm topology and the *strict topology*:

Definition 1.23. The *strict topology* on $\mathcal{L}_A(E, F)$ is the locally convex topology on $\mathcal{L}_A(E, F)$ generated by the family of semi-norms

$$t \mapsto \|tx\|, \text{ for } x \in E \text{ and } t \mapsto \|t^*y\|, \text{ for } y \in F.$$

This topology turns out to be very important, and there is many results of the classic theory which apply in this setting as well:

Proposition 1.24. Let E be a Hilbert A -module. Then the unit ball of $\mathbb{K}_A(E, F)$, $(\mathbb{K}_A(E, F))_1$, is strictly dense in the unit ball, $(\mathcal{L}_A(E, F))_1$, of $\mathcal{L}_A(E, F)$.

Proof.

Let (e_i) be an approximate identity of the C^* -algebra $\mathbb{K}_A(E)$. Then, for all $w\langle x, y \rangle \in E\langle E, E \rangle$ we see that

$$e_i w\langle x, y \rangle = e_i \Theta_{w, x}(y) \rightarrow \Theta_{w, x}(y) = w\langle x, y \rangle,$$

and hence $e_i x \rightarrow x$ for all $x \in E$, since $E\langle E, E \rangle \subseteq E$ is dense by 1.5. Then we clearly have, for $t \in (\mathcal{L}_A(E, F))_1$ that

$$\|t(e_i x - x)\| \rightarrow 0 \text{ and } \|e_i t^* y - t^* y\| \rightarrow 0,$$

for $x \in E$ and $y \in F$, so $te_i \rightarrow t$ strictly, and by 1.14 we see that $te_i \in (\mathbb{K}_A(E, F))_1$, finishing the proof. \square

1.3 UNITALIZATIONS AND THE MULTIPLIER ALGEBRA

We are almost ready to introduce the Multiplier Algebra of a C^* -algebra A , however, we must introduce some new terminology first

Definition 1.25. An ideal I of a C^* -algebra A is an *essential ideal* if it is non-zero and satisfies $I \cap J \neq 0$ for all non-zero ideals J of A .

And there is another commonly used equivalent formulation of the definition of essential ideals:

Lemma 1.26. Let I, J be non-zero ideals of a C^* -algebra A . Then the following holds:

1. $I^2 = I$,
2. $I \cap J = IJ$,
3. I is essential if and only if $aI = 0$ implies $a = 0$ for all $a \in A$.

Proof.

1: It holds that $I^2 \subseteq I$, since I is an ideal. For the other inclusion, note that if $a \geq 0$ is an element of I , then $a = (a^{\frac{1}{2}})^2 \in I^2$, so $I_+ \subseteq I^2$ hence $I = I^2$.

2: Note that $I \cap J = (I \cap J)^2$ by (1), and $(I \cap J)(I \cap J) \subseteq IJ \subseteq I \cap J$.

3: Assume that I is essential and $aI = 0$. Then $(a)I = (a) \cap I = 0$, where (a) is the ideal generated by a in A , and hence $(a) = 0$ so $a = 0$. For the converse, let $J \neq 0$ be any ideal of A and let $0 \neq a \in J$. By assumption this implies that $aI \neq 0$, so $(a)I = (a) \cap I \neq 0$, which shows that $J \cap I \neq 0$. \square

As mentioned earlier, it is a useful tool to be able to adjoin units to a non-unital C^* -algebra A . We formalize this process in the following definition:

Definition 1.27. A *unitization* of a C^* -algebra A is a pair (B, ι) consisting of a unital C^* -algebra B and an injective homomorphism $\iota: A \hookrightarrow B$ such that $\iota(A)$ is an essential ideal of B .

The most common way of adjoining a unit to a non-unital C^* -algebra A is to consider the vector space $A \oplus \mathbb{C}$ and endow it with a proper $*$ -algebra structure and give it a certain C^* -norm, see e.g., [Zhu93, Theorem 15.1]. This can also be done via the use of compact operators on A :

Example 1.28

Let $A^1 := A \oplus \mathbb{C}$ as a $*$ -algebra with $(x, \alpha)(y, \beta) := xy + \alpha y + \beta x + \alpha\beta$ and entrywise addition and involution. Identify A with $\mathbb{K}_A(A_A)$ inside $\mathcal{L}_A(A_A)$ via the left-multiplication operator, L , on A , and consider the algebra generated by 1 and $\mathbb{K}_A(A_A)$ in $\mathcal{L}_A(A_A)$. It is easy to see

that it is a C^* -algebra and that we may extend L to an isomorphism of $*$ -algebras between $\mathbb{K}_A(A_A) + \mathbb{C}$ and A^1 , which we turn into a C^* -algebra by stealing the norm:

$$\|(a, \alpha)\| = \sup \{ \|ax + \alpha x\| \mid \|x\| \leq 1, x \in A \}, \text{ for } (a, \alpha) \in A^1.$$

The pair (A^1, ι) , where $\iota: A \rightarrow A^1, a \mapsto (1, 0)$ is a unitalization of A : It is clear that it is injective, since $\|\iota(a)\| = \|L_a\| = \|a\|$ for all $a \in A$ and $\iota(A)$ is an ideal since $\mathbb{K}_A(A_A)$ is an ideal. It remains to be shown that it is essential:

Suppose that $(x, \beta)\iota(A) = 0$ so for all $a \in A$ we have $xa + \beta a = 0$. If $\beta = 0$ then $\|(x, 0)^*(x, 0)\| = \|x\|^2 = 0$ so $x = 0$ and $(x, \beta) = (0, 0)$. Assume that $\beta \neq 0$, then $-\frac{x}{\beta}a = a$ for all $a \in A$, so $a^* = a^* \left(-\frac{x}{\beta}\right)^*$, and hence $a = a \left(-\frac{x}{\beta}\right)^*$, since $a \in A$ is arbitrary. Letting $a = -\frac{x}{\beta}$, we see that $\frac{x}{\beta}$ is self-adjoint and hence a unit of A , a contradiction. Therefore $(x, \beta) = (0, 0)$ and $\iota(A)$ is an essential ideal of A^1 .

Example 1.29

The pair $(\mathcal{L}_A(A_A), L)$, $L: a \mapsto L_a$, is a unitalization of A - to see this we need only show that $\mathbb{K}_A(A_A)$ is essential in $\mathcal{L}_A(A_A)$: Suppose that $T\mathbb{K}_A(A_A) = 0$, so $TK = 0$ for all compact K on A , then with $\Theta_{x,y}: z \mapsto x\langle y, z \rangle = xy^*z$, we see by 1.14 that $T\Theta_{x,y} = \Theta_{Tx,y} = 0$ for all $x, y \in A$, which shows that for $x, y \in A$ we have $\Theta_{Tx,y}(y) = (Tx)(y^*y) = L_{Tx}(y^*y) = 0$, implying that $L_{Tx} = 0 \iff Tx = 0$ so $T = 0$.

And, it makes sense to talk about a 'largest' unitalization, in the sense that it has a certain universal property:

Definition 1.30. A unitalization (B, ι) of a C^* -algebra A is said to be *maximal* if to every other unitalization (C, ι') , there is a $*$ -homomorphism $\varphi: C \rightarrow B$ such that diagram:

$$\begin{array}{ccc} A & \xhookrightarrow{\iota} & B \\ & \searrow & \uparrow \exists \varphi \\ & \iota' & C \end{array} \quad (1.7)$$

commutes.

Definition 1.31. For a C^* -algebra A , we define the *multiplier algebra* of A to be $M(A) := \mathcal{L}_A(A_A)$.

It turns out that this is a maximal unitalization of A , as we shall see in a moment - but first we need a bit more work, for instance we need the notion of non-degenerate representations of a C^* -algebra on a Hilbert space to be extended to the case of Hilbert C^* -modules:

Definition 1.32. Let B be a C^* -algebra and E a Hilbert A -module. A homomorphism $\varphi: B \rightarrow \mathcal{L}_A(E)$ is *non-degenerate* if the set

$$\varphi(B)X := \text{Span} \{ \varphi(b)x \mid b \in B \text{ and } x \in E \},$$

is dense in E .

Example 1.33

In the proof of 1.24 we saw that the inclusion $\mathbb{K}_A(A_A) \subseteq \mathcal{L}_A(A_A)$ is non-degenerate for all C^* -algebras A .

Proposition 1.34. Let A and C be C^* -algebras, and let E denote a Hilbert A -module and let B be an ideal of C . If $\alpha: B \rightarrow \mathcal{L}_A(E)$ is a non-degenerate $*$ -homomorphism, then it extends uniquely to a $*$ -homomorphism $\bar{\alpha}: C \rightarrow \mathcal{L}_A(E)$. If further $\iota(B)$ is an essential ideal of C , then the extension is injective.

Proof.

The last statement is clear, since $\ker \bar{\alpha} \cap B = \ker \alpha \cap B = 0$ which implies that $\ker \bar{\alpha} = 0$, since B is essential. Let (e_j) be an approximate identity of B . Define for $c \in C$ the operator $\bar{\alpha}(c)$ on $\alpha(B)X$ by

$$\bar{\alpha}(c) \left(\sum_{i=1}^n \alpha(b_i)(x_i) \right) := \sum_{i=1}^n \alpha(cb_i)(x_i).$$

This is well-defined and bounded, for we see that

$$\left\| \sum_{i=1}^n \alpha(cb_i)(x_i) \right\| = \lim_j \left\| \sum_{i=1}^n \alpha(\underbrace{ce_j}_{\in B})(b_i)(x_i) \right\| \leq \|c\| \left\| \sum_{i=1}^n \alpha(b_i)(x_i) \right\|.$$

This extends to a bounded operator on all of E , since $\alpha(B)E$ is dense which also implies uniqueness of the extension. It is easy to see that $c \mapsto \bar{\alpha}(c)$ is a homomorphism. It remains to be shown that it is adjointable: Let $c \in C$ and $x, y \in E$, then

$$\langle \bar{\alpha}(c)x, y \rangle = \lim_j \langle \underbrace{\alpha(ce_j)}_{\in \mathcal{L}_A(E)} x, y \rangle = \lim_j \langle x, \alpha(ce_j)^* y \rangle = \lim_j \langle x, \alpha(e_j^* c^*) y \rangle = \langle x, \bar{\alpha}(c)y \rangle,$$

this shows that $\bar{\alpha}(c^*)$ is an adjoint of $\bar{\alpha}(c)$, hence it is a $*$ -homomorphism with values in $\mathcal{L}_A(E)$ \square

Corollary 1.35. The inclusion of $\mathbb{K}_A(A_A) \subseteq \mathcal{L}_A(A_A)$ is a maximal unitalization.

Proof.

In 1.29 we saw that $\mathbb{K}_A(A_A)$ is an essential ideal of $\mathcal{L}_A(A_A)$ and nondegeneracy was seen in 1.33. By 1.34, the corollary follows. \square

In particular, if $X = A_A$ and $C = M(B)$, then the above proposition guarantees an extension from B to $M(B)$.

We shall now see that the homomorphism provided by the universal property of a maximal unitalization is unique, this is the final ingredient we shall need to show that $M(A)$ is a maximal unitalization of A :

Lemma 1.36. If $\iota: A \hookrightarrow B$ is a maximal unitalization and $j: A \hookrightarrow C$ is an essential embedding, then the homomorphism $\varphi: C \rightarrow B$ of 1.30 is unique and injective.

Proof.

Suppose that $\varphi, \psi: C \rightarrow B$ such that $\varphi \circ j = \psi \circ j = \iota$. Then, for $c \in C$, we see that

$$\varphi(c)\iota(a) - \psi(c)\iota(a) = \varphi(c)\varphi(cj(a)) - \psi(c)\psi(cj(a)) = \varphi(cj(a)) - \psi(cj(a)) = 0,$$

for all $a \in A$, so essentiality of $\iota(A)$ in B and 1.26 implies that $\varphi = \psi$. For injectivity, note that $\ker \varphi \cap j(A) = 0$, hence $\ker \varphi = 0$, since $j(A)$ is essential in C . \square

We may finally show that $(M(A), L)$ is a maximal unitalization for all C^* -algebras A :

Theorem 1.37. For any C^* -algebra A , the unitalization $(M(A), L)$ is maximal, and unique up to isomorphism

Proof.

For maximality, suppose that $j: A \hookrightarrow C$ is an essential embedding of A in a C^* -algebra C . We know that L is nondegenerate, hence by 1.34 we obtain an extension $\bar{L}: C \hookrightarrow M(A)$ such that $\bar{L} \circ j = L$. For uniqueness, suppose that (B, ι) is a maximal unitalization of A . By 1.34 and maximality of (B, ι) we obtain the following commutative diagram

$$\begin{array}{ccc} & M(A) & \\ & \uparrow \exists! \bar{L} & \\ A & \xrightarrow{L} & B \\ & \downarrow \exists! \beta & \\ & M(A) & \end{array} \quad \begin{array}{c} \swarrow \text{id}_{M(A)} \\ \searrow \end{array} \quad (1.8)$$

The identity operator on $M(A)$ is by 1.34 the unique operator satisfying $L = \text{id}_{M(A)} \circ L$, but $\bar{L} \circ \beta \circ L = L$, so they are inverses of each other hence isomorphisms. \square

Often we want to be able to 'touch' the Multiplier Algebra of a C^* -algebra – and we can use the concretification as $\mathcal{L}_A(A_A)$, but there is (and other as well) another common way to describe it:

Proposition 1.38. Let A, C be C^* -algebras and E be a Hilbert C^* -module. Suppose that $\alpha: A \rightarrow \mathcal{L}_C(E)$ is an injective nondegenerate homomorphism. Then α extends to an isomorphism of $M(A)$ with the idealizer $\mathcal{I}(A)$ of $\alpha(A)$ in $\mathcal{L}_C(E)$:

$$\mathcal{I}(A) = \{T \in \mathcal{L}_C(E) \mid T\alpha(A) \subseteq \alpha(A) \text{ and } \alpha(A)T \subseteq \alpha(A)\}.$$

Proof.

It is clear that $\alpha(A)$ is an ideal of the idealizer $\mathcal{I}(A)$, which is in fact essential by nondegeneracy of α : If $T\alpha(A) = 0$ then $T\alpha(A)E = 0$ hence $T = 0$.

By 1.37 it suffices to show that $(\mathcal{I}(A), \alpha)$ is a maximal unitalization of A . Let $\iota: A \hookrightarrow B$ be an essential embedding of A into a C^* -algebra B . Let $\bar{\alpha}: B \hookrightarrow \mathcal{L}_C(E)$ denote the injective

extension of α from 1.34. We must show that $\bar{\alpha}(B) \subseteq \mathcal{I}(A)$: Let $b \in B$ and $a \in A$. Then, as $b\varphi(a) \in \varphi(A)$, we see that $\bar{\alpha}(b) \underbrace{\alpha(a)}_{=\bar{\alpha}(u(a))} = \bar{\alpha}(b\iota(a)) \in \alpha(A)$, as wanted. \square

This allows us to, given any faithful nondegenerate representation of A on a Hilbert space \mathcal{H} , to think of $M(A)$ as the idealizer of A in $\mathbb{B}(\mathcal{H})$, and it immediately allows us to describe the Multiplier algebra of $\mathbb{K}_A(E)$:

Corollary 1.39. For all C^* -algebras A and Hilbert A -modules, we have $M(\mathbb{K}_A(E)) \cong \mathcal{L}_A(E)$.

Proof.

This follows from 1.38: As we have seen the inclusion $\mathbb{K}_A(E) \subseteq \mathcal{L}_A(E)$ is nondegenerate and $\mathcal{I}(\mathbb{K}_A(E)) = \mathcal{L}_A(E)$ since the compacts is an ideal. In particular $\mathcal{L}_A(E)$ has the strict topology: $T_i \rightarrow T$ strictly if and only if $T_i K \rightarrow TK$ and $KT_i \rightarrow KT$ for all $K \in \mathbb{K}_A(E)$. \square

Using this, we can calculate both the adjointable operators and the Multiplier algebras in some settings:

Example 1.40

For the Hilbert \mathbb{C} -module \mathcal{H} , we obtain the identity that $M(\mathbb{K}(\mathcal{H})) = \mathbb{B}(\mathcal{H})$, as expected, since $\mathbb{B}(\mathcal{H})$ is the prototype of a 'large' abstract C^* -algebra.

A lot of the theory in functional analysis and the study of C^* -algebras is motivated by the study of abelian C^* -algebras of the form $C_0(\Omega)$ for a locally compact Hausdorff space. This construction is no exception: Unitalizations come naturally from compactifications, e.g., adjoining a unit to $C_0(\Omega)$ corresponds to the one-point compactification of Ω . It turns out that passing from $C_0(\Omega)$ to its multiplier algebra is connected to the largest compactification of Ω , namely the Stone-Ćech compactification $\beta\Omega$ of Ω , which in fact is the protoexample of the multiplier construction.

Example 1.41

If Ω is a locally compact Hausdorff space, then $M(C_0(\Omega)) \cong C_b(\Omega) = C(\beta\Omega)$.

Proof.

The unital C^* -algebra $C_b(\Omega)$ is isomorphic to $C(Y)$ for some compact Hausdorff space Y , which can be realised as $\beta\Omega$ (see [Ped12, p. 151]). Note that since $C_0(\Omega)$ separates points in Ω cf. Urysohn's lemma, it is an essential ideal of $C_b(\Omega)$, and the inclusion $C_0(\Omega) \hookrightarrow C_b(\Omega)$ is non-degenerate. Therefore 1.34 ensures a unique injection $*$ -homomorphism $\varphi: C_b(\Omega) \rightarrow M(C_0(\Omega))$.

For surjectivity, suppose that $g \in M(C_0(\Omega))$ and let $(e_i) \subseteq C_0(\Omega)$ denote an approximate identity. Without loss of generality, assume that $g \geq 0$ in $M(C_0(\Omega))$. Then, for $x \in \Omega$, we have $\{ge_i(x)\}_i \subseteq [0, \|g\|]$ and $ge_i(x)$ is increasing, since e_i is and therefore it has a limit, which we denote by $h(x)$, which is bounded above by $\|g\|$, and it satisfies $hf = \lim ge_i f = gf \in C_0(X)$ for all $f \in C_0(\Omega)$.

We claim that $t \mapsto h(t)$ is a continuous map: Suppose that $t_\alpha \rightarrow t \in \Omega$, and without loss of generality assume that $t_\alpha \in K$ for all α , for some compact neighborhood of T . Use Urysohn's lemma to pick $f \in C_0(\Omega)$ such that $f|_K = 1$. Then, since $hf \in C_0(\Omega)$ we have

$$h(t) = f(t)h(t) = (hf)(t) = \lim_{\alpha} hf(t_\alpha) = \lim_{\alpha} h(t_\alpha),$$

so h is continuous. Let $f \in C_0(\Omega)$, then $\varphi(h)f = \varphi(h)\varphi(f) = \varphi(hf) = hf = gf$, so by non-degenerancy we see that $\varphi(h) = g$ so $g \in C_b(\Omega)$. \square

In fact, one can show that when equipped with suitable orderings, then there is a correspondance between compactifications of locally compact spaces Ω and unitalizations of their associated C^* -algebras $C_0(\Omega)$.

One of the main interests in introducing the above discussed results will be clearer later on, but we will emphasize that it really is the strict topology on $M(A)$. This will be useful, since it coincides with another useful topology on bounded sets, called the $*$ -strong topology, which we will define in a moment. This will be particularly useful when we recall that $\mathbb{B}(\mathcal{H}) = M(\mathbb{K}(\mathcal{H}))$, so that $\mathbb{B}(\mathcal{H})$ has the strict topology – this will allow us to expand and unify the representation theory of C^* -algebras and locally compact groups, which is the cornerstone of the setting which this thesis will cover.

Definition 1.42. Given a Hilbert A -module, the $*$ -strong topology on $\mathcal{L}_A(E)$ is the topology for which $T_i \rightarrow T$ if and only if $T_i x \rightarrow T x$ and $T_i^* x \rightarrow T^* x$ for all $x \in E$. It has a neighborhood basis consisting of sets of the form

$$V(T, x, \varepsilon) := \{S \in \mathcal{L}_A(E) \mid \|Sx - Tx\| + \|S^*x - T^*x\| < \varepsilon\},$$

for $T \in \mathcal{L}_A(E)$, $x \in E$ and $\varepsilon > 0$.

We will use $M_s(A)$ to mean $M(A)$ equipped with the strict topology, and we will write $\mathcal{L}_A(E)_{*-s}$ to mean we equip it with the $*$ -strong topology. for $A = \mathbb{C}$, we see that $T_i \rightarrow T \in \mathbb{B}(\mathcal{H})$ in the $*$ -strong topology if and only $T_i \rightarrow T$ and $T_i^* \rightarrow T^*$ in the strong operator topology. We said that we only have interest in the strict topology and the norm topology on $\mathcal{L}_A(E)$, and this is because the $*$ -strong topology and strict topology coincides on bounded subsets:

Proposition 1.43. If E is a Hilbert A -module, if $T_i \rightarrow T \in \mathcal{L}_A(E)$ strictly, then $T_i \rightarrow T$ $*$ -strongly. Moreover, on norm bounded subsets the topologies coincide.

Proof.

Suppose that $T_i \rightarrow T$ strictly. For $x \in E$, write $x = y\langle y, y \rangle$ for some unique $y \in E$ using Proposition 1.22. Let ${}_{\mathbb{K}_A(E)}\langle x, y \rangle = \Theta_{x,y} \in \mathbb{K}_A(E)$ be the associated $\mathbb{K}_A(E)$ -valued inner-product on E from Proposition 1.18, so $x = {}_{\mathbb{K}_A(E)}\langle y, y \rangle(y)$. By definition of the strict topology on $\mathcal{L}_A(E) = M(\mathbb{K}_A(E))$, we see that

$$T_i(x) = T_i \circ {}_{\mathbb{K}_A(E)}\langle y, y \rangle(y) \rightarrow T \circ {}_{\mathbb{K}_A(E)}\langle y, y \rangle = T(x).$$

Continuity of adjunction shows that $T_i^* \rightarrow T^*$ as well, hence also $T_i^* \rightarrow T^*$ strongly, so $T_i \rightarrow T$ $*$ -strongly.

Suppose now (T_i) is bounded in norm by $K \geq 0$. For $x, y \in E$, if $T_i x \rightarrow Tx$ in norm, then $T_i \Theta_{x,y} \rightarrow T \Theta_{x,y}$ in norm:

$$\|T_i \Theta_{x,y} - T \Theta_{x,y}\| \leq \sup_{\|z\| \leq 1} \|T_i x - Tx\| \|\langle y, z \rangle\| \rightarrow 0,$$

and similarly $T_i^* \Theta_{x,y} \rightarrow T^* \Theta_{x,y}$. By approximating compact operators with finite linear combinations of $\Theta_{x,y}$'s, an easy $\frac{\varepsilon}{3N} > 0$ argument shows that $T_i K \rightarrow TK$ and $KT_i \rightarrow KT$ for $K \in \mathbb{K}_A(E)$ and similarly $T_i^* K \rightarrow T_i^* K$ and $KT_i^* \rightarrow KT$. \square

Integral Forms And Representation Theory

Suppose that you are given a discrete C^* -dynamical system (A, G, α) , here discrete means that G is discrete. It is not hard to extend representations of G and A to the group ring $\mathbb{C}_C(G, A)$, and thus create new C^* -algebras through completion of it. However, when G is not discrete, we run into issues since we can not assume that a unitary representation of G is continuous in norm, which is required by classic constructions seen e.g., in [BO08]. We will in this chapter develop the necessary theory to define the non-discrete analogues of these techniques.

Crossed Products with Topological Groups

3.1 CROSSED PRODUCTS

Throughout this chapter, we let G be a locally compact topological group and A a C^* -algebra, with no added assumptions unless otherwise specified. We will write $G \curvearrowright_\alpha A$ to specify that $\alpha: G \rightarrow \text{Aut}(A)$ is an action of G on A , i.e., a strongly continuous group homomorphism. We will always fix a base left Haar measure μ on G , whose integrand we will denote by dt , and with modular function $\Delta: G \rightarrow (0, \infty)$.

In analysis, an object of interest is the group algebra $L^1(G)$ for locally compact groups G . One can turn it into a $*$ -algebra by showing that the convolution gives rise to a well-defined multiplication, and one can use the modular function to define an involution. Analogously to this, we do the same for A valued functions:

Definition 3.1. Suppose that $G \curvearrowright_\alpha A$. We let

$$C_c(G, A) := \{f: G \rightarrow A \mid f \text{ continuous and compactly supported}\}.$$

For $f, g \in C_c(G, A)$, we define the α -twisted convolution of f and g at $t \in G$ by

$$(f *_\alpha g)(t) := \int_G f(s) \alpha_s(g(s^{-1}t)) ds,$$

and we define an α -twisted convolution of $f \in C_c(G, A)$ at $t \in G$ by

$$f^*(t) := \Delta(t^{-1}) \alpha_t(f(t^{-1})^*).$$

Straight forward calculations similar to the one classic ones show that $C_c(G, A)$ becomes a $*$ -algebra with multiplication given by the α -twisted convolution and involution given by the α -twisted involution. We denote the associated $*$ -algebra by $C_c(G, A, \alpha)$.

To $f \in C_c(G, A, \alpha)$, we associate the number $\|f\|_1 \in [0, \infty)$ by

$$\|f\|_1 := \int_G \|f(t)\| dt.$$

Straightforward calculations show that $f \mapsto \|f\|_1$ is a norm, and we denote the completion of $C_c(G, A, \alpha)$ in $\|\cdot\|_1$ by $L^1(G, A, \alpha)$.

For $G \curvearrowright_\alpha A$ and a covariant representation (π, \mathcal{H}) on some Hilbert space \mathcal{H} , we define for $f \in C_c(G, A, \alpha)$ the operator I_f on \mathcal{H} point-wise, i.e., for $\xi, \eta \in \mathcal{H}$

$$\langle I_f \xi, \eta \rangle = \int_G \langle \pi(f(s)) U_s \xi, \eta \rangle ds,$$

and we will write $\int_G \pi(f(s)) U_s ds := I_f$. We denote the map $f \mapsto I_f$ by $\pi \rtimes U$.

Lemma 3.2. The map $\pi \rtimes U$ is a $*$ -representation of $C_c(G, A, \alpha)$ called *the integrated form of π and U* . It is L^1 -norm decreasing, i.e., for $f \in C_c(G, A, \alpha)$ we have

$$\|\pi \rtimes U(f)\| \leq \|f\|_1.$$

Proof.

Let $f \in C_c(G, A, \alpha)$ and $\xi, \eta \in \mathcal{H}$. Then

$$|\langle \pi \rtimes U(f) \xi, \eta \rangle| \leq \int_G |\langle \pi(f(s)) U_s \xi, \eta \rangle| ds \leq \int_G \|f(s)\| \|\xi\| \|\eta\| ds,$$

so that $\|\pi \rtimes U(f)\| \leq \|f\|_1$. Let $f, g \in C_c(G, A, \alpha)$

INTEGRATION THEORY IN GROUPS

Integration over groups plays a vital role in the theory developed and processed throughout this thesis. Therefore, we will build some of the cornerstone results in this theory, which will be used frequently. We will by G denote an arbitrary locally compact group, and by X an arbitrary Banach space. We will fix a left-Haar measure μ on G , whose integrand we denote by dt .

For $f \in C_c(G)$ and $x \in X$, we denote by $f \otimes x$ the map $G \ni t \mapsto f(t)x \in X$. It is clear that then $f \otimes x \in C_c(G, X)$.
